

DSLsofMath 2017: Assignment 2

Optimisation using Newton's method

This assignment is based on the lectures from weeks 3 and 4 (the *FunExp* type, *eval*, *derive*, *D*, tupling, homomorphisms, *FD*, *apply*, ...) so it pays off to work through those notes carefully.

1. The evaluation of the second derivative is given by

$$eval'' = eval' \circ derive = eval \circ derive \circ derive$$

- (a) Show that *eval''* is not a homomorphism from *FunExp* to *FunSem* = $\mathbb{R} \rightarrow \mathbb{R}$.
- (b) Given the following types

```
type Tri a      = (a, a, a)
type TriFun a = Tri (a → a)  -- = (a → a, a → a, a → a)
type FunTri a = a → Tri a    -- = a → (a, a, a)
```

Define instances of *Num*, *Fractional*, *Floating*, for *Tri a* and define a homomorphism *evalDD* from *FunExp* to *FunTri a* (for any type *a* in *Floating*). You don't need to prove that it is a homomorphism in this part.

- (c) Show that *evalDD* is a homomorphism for the case of multiplication.
2. Newton's method allows us to find zeros of a large class of functions in a given interval. The following description of Newton's method follows Bird and Wadler [1988], page 23:

```
type ℝ = Double
newton :: (ℝ → ℝ) → ℝ → ℝ → ℝ
newton f ε x = if abs fx < ε
               then x
               else if fx' ≠ 0 then newton f ε next
               else newton f ε (x + ε)

where fx      = f x
      fx'     = undefined  -- f' x (derivative of f at x)
      next    = x - (fx / fx')
```

- (a) Implement Newton's method, using *Tri* $\mathbb{R} \rightarrow \text{Tri } \mathbb{R}$ for the type of the first argument. In other words, use the code above to implement

```
newtonTri :: (Tri ℝ → Tri ℝ) → ℝ → ℝ → ℝ
```

in order to obtain the appropriate value for *f' x*.

(b) Test your implementation on the following functions:

```
test0 x = x^2           -- one (double) zero, in 0
test1 x = x^2 - 1       -- two zeros, in -1 and 1
test2 = sin             -- many, many zeros ( $n * \pi$ )
test3 n x y = y^n - constTri x -- test3 n x specifies the nth root of x
-- where constTri is the embedding of Const
```

For each of these functions, apply Newton's method to a number of starting points from a sensible interval. For example:

```
map (newton test1 0.001) [-2.0, -1.5 .. 2.0]
```

but be aware that the method might not always converge!

For debugging is advisable to implement *newton* in terms of the minor variation *newtonList*:

```
newton f  $\epsilon$  x = last (newtonList f  $\epsilon$  x)
newtonList :: (Fractional a, Ord a)  $\Rightarrow$  (a  $\rightarrow$  a)  $\rightarrow$  a  $\rightarrow$  a  $\rightarrow$  [a]
newtonList f  $\epsilon$  x = x : if ... then [] else ...
```

3. We can find the optima of a twice-differentiable function on an interval by finding the zeros of its derivative on that interval, and checking the second derivative. If x_0 is a zero of f' , then

- if $f'' x_0 < 0$, then x_0 is a maximum
- if $f'' x_0 > 0$, then x_0 is a minimum
- if $f'' x_0 = 0$, then, if $f'' (x_0 - \epsilon) * f'' (x_0 + \epsilon) < 0$ (i.e., f'' changes its sign in the neighbourhood of x_0), x_0 is an inflection point (not an optimum)
- otherwise, we don't know

Use Newton's method to find the optima of the test functions from point 2. That is, implement a function

```
optim :: (Tri  $\mathbb{R} \rightarrow$  Tri  $\mathbb{R}$ )  $\rightarrow$   $\mathbb{R} \rightarrow \mathbb{R} \rightarrow$  Result  $\mathbb{R}$ 
```

so that *optim* $f \epsilon x$ uses Newton's method to find a zero of f' starting from x . If y is the result (i.e. $f' y$ is within ϵ of 0), then check the second derivative, returning *Maximum* y if $f'' y < 0$, *Minimum* y if $f'' y > 0$, and *Dunno* y if $f'' = 0$.

As before, use several starting points.

Hint: you might want to modify the code you've written for Newton's method at point 2.

Formalities

Submission: Assignments are to be submitted via Fire: <https://dslm-lp3-18.frs.cse.chalmers.se>

Deadline: Tuesday, 2017-02-27, 23:59.

Grading: Discussions with each of the teams during one of the slots 2018-03-02.
