DSLsofMath 2017: Assignment 2

Optimisation using Newton's method

1. The evaluation of the second derivative is given by

```
eval'' = eval' \circ derive = eval \circ derive \circ derive
```

- (a) Show that eval'' is not a homomorphism.
- (b) What datatype is needed to have a homomorphism from *Expr* in this case? Show this for the case of multiplication.
- (c) What datatype is needed for the homomorphism that is analogous to apply? Give instances of the numerical classes (Num, Fractional, Floating) for this datatype, as well as an embedding of Const and Id.
- 2. Newton's method allows us to find zeros of a large class of functions in a given interval. The following description of Newton's method follows Bird and Wadler [1988], page 23:

```
newton :: (Double 	o Double) 	o Double 	o Double 	o Double
newton \ f \ \epsilon \ x = \mathbf{if} \ |fx| < \epsilon
\mathbf{then} \ x
\mathbf{else} \ \mathbf{if} \ fx' \not\equiv 0 \ \mathbf{then} \ newton \ f \ \epsilon \ next
\mathbf{else} \ newton \ f \ \epsilon \ (x + \epsilon)
\mathbf{where} \ fx = f \ x
fx' = undefined \ --f' \ x \ (derivative \ of \ f \ at \ x)
next = x - (fx \ / fx')
```

Implement Newton's method, using the datatype you introduced above for computing the derivatives. In other words, use the code above to implement

```
newton :: (FDD\ Double \rightarrow FDD\ Double) \rightarrow Double \rightarrow Double \rightarrow Double
```

where FDD a is the datatype from above, in order to obtain the appropriate value for f' x. Test your implementation on the following functions:

```
\begin{array}{lll} test0 = x^2 & \text{-- one (double) zero, in 0} \\ test1 = x^2 - 1 & \text{-- two zeros, in -1 and 1} \\ test2 = sin & \text{-- many, many zeros } (n*\pi) \\ test3 \ n \ x \ y = y^n - fddId \ x & \text{-- nth root of } x \\ \text{-- where } fddId \ \text{is the embedding of } Id \end{array}
```

For each of these functions, apply Newton's method to a number of starting points from a sensible interval. For example:

```
fmap (newton test1 0.001) [-2.0, -1.5..2.0]
```

but be aware that the method might not always converge!

- 3. We can find the optima of a twice-differentiable function on an interval by finding the zeros of its derivative on that interval, and checking the second derivative. If x_0 is a zero of f', then
 - if $f'' x_0 < 0$, then x_0 is a maximum
 - if $f''(x_0) > 0$, then x_0 is a minimum
 - if $f''(x_0 = 0)$, then, if $f''(x_0 \epsilon) * f''(x_0 + \epsilon) < 0$ (i.e., $f''(x_0 + \epsilon) < 0$), $f''(x_0 + \epsilon) < 0$ (i.e., $f''(x_0 + \epsilon) < 0$), $f''(x_0 + \epsilon) < 0$ (i.e., $f''(x_0 + \epsilon) < 0$).
 - otherwise, we don't know

Use Newton's method to find the optima of the test functions from point 2. That is, implement a function

```
optim :: (FDD\ Double \rightarrow FDD\ Double) \rightarrow Double \rightarrow Double \rightarrow Result\ Double
```

so that optim $f \in x$ uses Newton's method to find a zero of f' starting from x. If y is the result (i.e. f' y is within ϵ of 0), then check the second derivative, returning Maximum y if f'' > 0, Minimum y if f'' > 0, and Dunno y if f'' = 0.

As before, use several starting points.

Hint: you might want to modify the code you've written for Newton's method at point 2.

Formalities

Submission: Assignments are to be submitted via Fire:

https://dsls-lp3-17.frs.cse.chalmers.se/login

Deadline: Tuesday, 2017-02-28, 23:59.

Grading: Discussions with each of the teams during the exercises session of Friday, 2017-03-03.
